Spacecraft Relative Attitude Formation Tracking on $SO(3)$
Based on Line-of-Sight Measurements

Tse-Huai Wu, Brien Flewelling, Fred Leve, and Taeyoung Lee*

Abstract—Relative attitude formation control systems are developed for multiple spacecraft, based on the line-of-sight measurements between spacecraft in formation. The proposed control systems are unique in the sense that they do not require constructing the full attitudes of spacecraft and comparing them to obtain the relative attitudes indirectly. Instead, the control inputs are directly expressed in terms of line-of-sight measurements to control relative attitude formation precisely and efficiently. It is shown that the zero equilibrium of the relative attitude tracking errors is almost globally asymptotically stable. The desirable properties are illustrated by numerical examples, including an image processing routine to simulate vision-based line-of-sight sensors.

I. INTRODUCTION

The coordinated control of multiple spacecraft in formation has been widely studied, as there are distinct advantages [1], [2]. Noticeable contributions on relative attitude control may be divided into leader-follower strategy [3], [4], behavior-based control [5], [6], and virtual structures [7], [8].

The aforementioned control systems for spacecraft attitude formation control have distinct features, but all of them are based on a common framework: the absolute attitude of each spacecraft with respect to an inertial frame is measured independently by using a local attitude sensor such as star trackers, and those measurements are transmitted to other spacecraft to determine relative attitudes by comparison.

This causes restrictions on the performance of coordinated spacecraft. First, all of spacecraft should be equipped with possibly expensive hardware systems to determine the absolute attitude completely. This may increase the overall cost of development significantly. Second, attitude formation is indirectly controlled by comparing the absolute attitudes of multiple spacecraft in the formation. This results in a fundamental limitation on the accuracy of attitude formation control systems, since measurement errors of multiple sensors are accumulated when determining relative attitudes.

Vision-based sensors have been widely applied for navigation of autonomous vehicles, where low-cost optical sensors are used to extract visual features to localize a vehicle [9]. In particular, it has been shown that line-of-sight (LOS) measurements between spacecraft in formation determine the relative attitudes completely. An extended Kalman filter for relative attitude is developed based on LOS observations [10]. The LOS measurements are also used for relative attitude determination of multiple vehicles [11], [12].

In this paper, a relative attitude formation control scheme is developed based on LOS measurements. Spacecraft in formation measure the LOS toward other spacecraft such that relative attitude between them asymptotically track a given desired relative attitude. Compared to other spacecraft attitude formation control systems, the proposed relative attitude control systems is unique in the sense that control inputs are directly expressed in terms of LOS measurements, and it does not require determining the full absolute attitude of spacecraft in formation or the full relative attitude between them. Therefore, relative attitudes are directly controlled, while utilizing the desirable features of vision-based sensors: they have higher accuracies at a relatively low cost, and they also have long-term stability requiring no corrections in measurements as opposed to gyros.

Compared with the preliminary work for relative attitude stabilization between two spacecraft [13], the control system proposed in this paper requires extensive analyses to take into full consideration of stability of time-varying systems for tracking, and the network structures between multiple spacecraft. The paper also provides stronger exponential stability, and numerical simulations with image processing.

Another distinct feature of the proposed relative attitude control system is that it is constructed on the special orthogonal group, $SO(3)$. Attitude control systems developed on minimal representations, such as Euler-angles, have singularities, and therefore their performance for large angle rotational maneuvers is severely limited. Quaternions do not have singularities, the ambiguity in representing attitude should be carefully resolved. By following geometric control approaches [14], [15], the proposed control system is developed in a coordinate-free fashion, and it does not have any singularity or ambiguity.

In this paper, proofs are relegated to [16] due to page limit.

II. PROBLEM FORMULATION

A. Spacecraft Attitude Formation Configuration

Consider an arbitrary number $n$ of spacecraft in formation. Each spacecraft is considered as a rigid body, and an inertial reference frame and body-fixed frames are defined. The attitude of each spacecraft is the orientation of its body-fixed frame with respect to the inertial reference frame, and it is represented by a rotation matrix in the special orthogonal
Each spacecraft measures the LOS from itself toward the other assigned spacecraft. A LOS observation is represented by a unit vector in the two-sphere, defined as
\[ S^2 = \{ s \in \mathbb{R}^3 \mid \|s\| = 1 \}. \]

For \( i, j \in \{1, \ldots, n\} \) and \( i \neq j \), define
\[ R_i \in \text{SO}(3) \]
the absolute attitude for the \( i \)-th spacecraft, representing the linear transformation from the \( i \)-th body-fixed frame to the inertial reference frame,
\[ s_{ij} \in S^2 \]
the unit vector toward the \( j \)-th spacecraft from the \( i \)-th spacecraft, represented in the inertial frame,
\[ b_{ij} \in S^2 \]
the LOS direction observed from the \( i \)-th spacecraft to the \( j \)-th spacecraft, represented in the inertial frame,
\[ Q_{ij} \in \text{SO}(3) \]
the relative attitude of the \( i \)-th spacecraft with respect to the \( j \)-th spacecraft,
\[ Q^d_{ij} \in \text{SO}(3) \]
the desired relative attitude for \( Q_{ij} \).

According to these definitions, the directions of the relative positions \( s_{ij} \) in the inertial reference frame are related to the LOS observation \( b_{ij} \) in the \( i \)-th body-fixed frame as follows:
\[ s_{ij} = R_i b_{ij}, \quad b_{ij} = R^T_i s_{ij}. \quad (1) \]

In short, \( b_{ij} \) represents the LOS observation of \( s_{ij} \), observed from the \( i \)-th body. The relative attitude is given by
\[ Q_{ij} = R^T_i R_i, \quad (2) \]
which represents the linear transformation of the representation of a vector from the \( i \)-th body fixed frame to the \( j \)-th body-fixed frame. Note that \( Q_{ij} = Q^T_{ji} \).

To assign a set of LOS that should be measured for each spacecraft, a graph \((\mathcal{N}, \mathcal{E})\) is defined as follows. Each spacecraft is considered as a node, and the set of nodes is given by \( \mathcal{N} = \{1, \ldots, n\} \). The set of edges \( \mathcal{E} \subseteq \mathcal{N} \times \mathcal{N} \) is defined such that the relative attitude between the \( i \)-th spacecraft and the \( j \)-th spacecraft is directly controlled if \( (i, j) \in \mathcal{E} \). It is undirected, i.e., \( (i, j) \in \mathcal{E} \iff (j, i) \in \mathcal{E} \).

For each pair of two spacecraft in the edge set, another third spacecraft is assigned by the assignment map \( \rho : \mathcal{E} \to \mathcal{N} \). As the edge set is undirected, the assignment map is symmetric, i.e., \( \rho(i, j) = \rho(j, i) \).

For convenience, the edge set and the image of the assignment map are combined to form the assignment set:
\[ \mathcal{A} = \{(i, j, k) \in \mathcal{E} \times \mathcal{N} \mid (i, j) \in \mathcal{E}, k = \rho(i, j)\}. \quad (3) \]

Let the measurement set \( \mathcal{L}_i \) be the set of LOS measured from the \( i \)-th spacecraft, and let the communication set \( \mathcal{C}_{ij} \) be the LOS transferred from the \( i \)-th spacecraft to the \( j \)-th spacecraft.

**Assumption 1:** The configuration of the relative positions is fixed, i.e., \( s_{ij} = 0 \) for all \( i, j \in \mathcal{N} \) with \( i \neq j \).

**Assumption 2:** The third spacecraft assigned to each edge does not lie on the line joining two spacecraft connected by the edge, i.e., \( s_{ik} \times s_{jk} \neq 0 \) for every \( (i, j, k) \in \mathcal{A} \).

**Assumption 3:** The measurement set of the \( i \)-th spacecraft is
\[ \mathcal{L}_i = \{b_{ij}, b_{ik} \in S^2 \mid (i, j, k) \in \mathcal{A}\}. \quad (4) \]

**Assumption 4:** The communication set from the \( i \)-th spacecraft to the \( j \)-th spacecraft is given by
\[ \mathcal{C}_{ij} = \begin{cases} \{b_{ij}, b_{ip(i,j)}\} & \text{if } (i, j) \in \mathcal{E}, \\ \emptyset & \text{otherwise.} \end{cases} \quad (5) \]

**Assumption 5:** In the edge set, spacecraft are paired serially by daisy-chaining.

The first assumption reflects the fact that this paper does not consider the translational dynamics of spacecraft, and we focus on the rotational attitude dynamics only. The proposed control input does not depend on the values of \( s_{ij} \), but its stability analyses is based on the first assumption that \( s_{ij} \) is fixed. The second assumption is required to determine the relative attitude between two spacecraft paired in the edge set from the assigned LOS measurements. The third assumption states that each spacecraft measures the LOS toward the paired spacecraft in the edge set, and the LOS toward the third spacecraft assigned to each pair by the assignment map. The fourth assumption implies that a spacecraft communicate only with the spacecraft paired with itself. The last assumption is made to simplify stability analysis, and the proposed relative attitude formation control system can be extended for other network topologies.

An example for formation of four spacecraft satisfying these assumptions are illustrated at Figure 1, where
\[ \mathcal{A} = \{(1, 2, 3), (2, 1, 3), (2, 3, 1), (3, 2, 1), (3, 4, 2), (4, 3, 2)\}. \]

The measurement sets and the communication sets can be determined by (4) and (5) from \( \mathcal{A} \). For example, for the third spacecraft, we have \( \mathcal{L}_3 = \{b_{31}, b_{32}, b_{34}\}, \mathcal{C}_{32} = \{b_{32}, b_{31}\}, \) and \( \mathcal{C}_{34} = \{b_{34}, b_{32}\} \).
B. Spacecraft Attitude Dynamics

The equations of motion for the attitude dynamics of each spacecraft are given by
\[
J_i \ddot{\Omega}_i + \Omega_i \times J_i \dot{\Omega}_i = u_i, \quad (6)
\]
\[
\dot{R}_i = R_i \dot{\Omega}_i, \quad (7)
\]
where \( J_i \in \mathbb{R}^{3 \times 3} \) is the inertia matrix of the \( i \)-th spacecraft, and \( \Omega_i \in \mathbb{R}^3 \) and \( u_i \in \mathbb{R}^3 \) are the angular velocity and the control moment of the \( i \)-th spacecraft, respectively.

The hat map \( \hat{\cdot} : \mathbb{R}^3 \to \mathfrak{so}(3) \) transforms a vector in \( \mathbb{R}^3 \) to a \( 3 \times 3 \) skew-symmetric matrix such that \( \hat{x}y = (x) y = x \times y \) for any \( x, y \in \mathbb{R}^3 \). The inverse of the hat map is denoted by the vee map \( \check{\cdot} : \mathfrak{so}(3) \to \mathbb{R}^3 \). Throughout this paper, the 2-norm of a matrix \( A \) is denoted by \( \| A \| \), and the dot product of two vectors is denoted by \( x \cdot y = x^T y \). The maximum eigenvalue and the minimum eigenvalue of \( J_i \) are denoted by \( \lambda_{M_i} \) and \( \lambda_{m_i} \), respectively.

III. RELATIVE ATTITUDE TRACKING BETWEEN TWO SPACECRAFT

We first consider a simpler case of controlling the relative attitude between two spacecraft. Based on the results of this section, relative attitude formation control systems are developed later. As a concrete example, we develop a control system for the relative attitude between Spacecraft 1 and Spacecraft 2, namely \( Q_{12} = R_{12}^T R_1 \) illustrated at Figure 1.

The corresponding edge set, assignment set and measurement sets used in this section are given by
\[
E = \{(1, 2), (2, 1)\}, \quad A = \{(1, 2, 3), (2, 1, 3)\}, \quad (8)
\]
\[
L_1 = C_{12} = \{b_{12}, b_{13}\}, \quad L_2 = C_{21} = \{b_{21}, b_{23}\}. \quad (9)
\]

Suppose that a desired relative attitude \( Q_{12}^d(t) \) is given as a smooth function of time. It satisfies the kinematic equation:
\[
\dot{Q}_{12}^d = Q_{12}^d \dot{\Omega}_{12}^d, \quad (10)
\]
where \( \Omega_{12}^d \) is the desired relative angular velocity. Note that these also yield \( Q_{12}^d = (Q_{12}^d)^T \) from (2), and it satisfies
\[
\dot{Q}_{21}^d = Q_{21}^d \dot{\Omega}_{21}^d, \quad (11)
\]
where \( \Omega_{21}^d = -Q_{12}^d \Omega_{12}^d \).

The goal is to design control inputs \( u_1, u_2 \) in terms of the LOS measurements in \( L_1 \cup L_2 \) such that \( Q_{12} \) asymptotically follows \( Q_{12}^d \), i.e., \( Q_{12}(t) \to Q_{12}^d(t) \) as \( t \to \infty \).

A. Kinematics of Relative Attitudes and Lines-of-Sight

For any \( i, j \in N \), the time-derivative of the relative attitude is given from (7), by
\[
\dot{Q}_{ij} = -\dot{\Omega}_i R_j^T R_i + R_j^T R_i \dot{\Omega}_i = Q_{ij} \dot{\Omega}_i - \Omega_i Q_{ij} = Q_{ij}(\Omega_i - Q_{ij} \Omega_{ij})^\wedge = Q_{ij} \hat{\Omega}_{ij}, \quad (12)
\]
where the relative angular velocity \( \Omega_{ij} \in \mathbb{R}^3 \) of the \( i \)-th spacecraft with respect to the \( j \)-th spacecraft is defined as
\[
\Omega_{ij} = \dot{\Omega}_i - Q_{ij}^T \dot{\Omega}_j, \quad (13)
\]
From (1) and (7), the time-derivative of the LOS measurement \( b_{ij} \) is given by
\[
\dot{b}_{ij} = \dot{R}_i T s_{ij} = -\dot{\Omega}_i T s_{ij} = \dot{b}_{ij} \times \Omega_i. \quad (14)
\]
Let \( b_{ijk} \in \mathbb{R}^3 \) be \( b_{ijk} = b_{ij} \times b_{ik} \). From (14), it can be shown that
\[
\dot{b}_{ijk} = (b_{ij} \times \Omega_i) \times b_{ik} + b_{ij} \times (b_{ik} \times \Omega_i) = -(\Omega_i \times b_{ik}) b_{ij} + (\Omega_i \cdot b_{ij} b_{ik}) = b_{ijk} \times \Omega_i. \quad (15)
\]

B. Relative Attitude Tracking

It has been shown that four LOS measurements \( \{b_{12}, b_{13}, b_{23}\} \) completely determine the relative attitude \( Q_{12} \) from the following constraints [13]:
\[
\frac{b_{23} - Q_{12} b_{21}}{\| b_{23} \|} = \frac{Q_{12} b_{213}}{\| b_{213} \|}. \quad (16)
\]
These are derived from the fact that four unit vectors, namely \( \{s_{12}, s_{13}, s_{21}, s_{23}\} \) lie on the sides of a triangle composed of three spacecraft. The first constraint (16) states that the unit vector from Spacecraft 1 to Spacecraft 2 is exactly opposite to the unit vector from Spacecraft 2 to Spacecraft 1, i.e., \( s_{12} = -s_{21} \). The second constraint (17) implies that the plane spanned by \( s_{12} \) and \( s_{13} \) should be co-planar with the plane spanned by \( s_{21} \) and \( s_{23} \). These geometric constraints are simply expressed with respect to the first body-fixed frame to obtain (16) and (17). For given LOS measurements \( \{b_{12}, b_{13}, b_{21}, b_{23}\} \), the relative attitude \( Q_{12} \) is uniquely determined by solving (16) and (17) for \( Q_{12} \).

We develop a relative attitude tracking control system based on these two constraints. More explicitly, control inputs are chosen such that two constraints are satisfied when the relative attitude is equal to its desired value. As both constraints are conditions on unit vectors, controller design is similar to tracking control on the two-sphere. From now on, variables related to the first constraint (16) (resp., the second constraint (17)) are denoted by the sub- or super-script \( \alpha \) (resp., \( \beta \)).

First, configuration error functions that represent the errors in satisfaction of (16) and (17) are defined as
\[
\Psi_{12}^\alpha = \frac{1}{2} \| b_{21} + Q_{12} b_{12} \|^2 = 1 + b_{21} \cdot Q_{12} b_{12}, \quad (18)
\]
\[
\Psi_{12}^\beta = 1 + \frac{1}{a_{12}} b_{213} \cdot Q_{12} b_{213}, \quad (19)
\]
where \( a_{12} = a_{21} \triangleq \| b_{213} \| \| b_{123} \| \in \mathbb{R} \). Since \( \| b_{ijk} \| = \| b_{ij} \times b_{ik} \| = \| R_i^T s_{ij} \times R_i^T s_{ik} \| = \| s_{ij} \times s_{ik} \| \), the constant \( a_{12} \) is fixed according to Assumption 1, and it is non-zero from Assumption 2. Next, we define the configuration error vectors as
\[
e_{12} = (Q_{21} b_{21}) \times b_{12}, \quad e_{12}^\alpha = (Q_{12} b_{12}) \times b_{21}, \quad (20)
e_{12}^\beta = \frac{1}{a_{12}} (Q_{21} b_{213}) \times b_{213}, \quad e_{12}^\gamma = \frac{1}{a_{21}} (Q_{12} b_{213}) \times b_{213}. \quad (21)
As \( b_{12}, b_{21} \) are unit vectors, and from the definition of \( a_{12}, a_{21} \), we can show that \( \| e_{\alpha 12} \|, \| e_{\alpha 21} \|, \| e_{\beta 12} \|, \| e_{\beta 21} \| \leq 1 \).

We also define the angular velocity errors:

\[
e_{\Omega_1} = \Omega_1 - \Omega_1^d, \quad e_{\Omega_2} = \Omega_2 - \Omega_2^d,\]

where the desired absolute angular velocities \( \Omega_1^d, \Omega_2^d \) are chosen such that

\[
\Omega_1^d(t) = \Omega_1(t) - Q_{21}^d(t) \Omega_2^d(t).\]

Any desired absolute angular velocities satisfying (23) can be chosen. For example, they can be selected as

\[
\Omega_1(t) = \frac{1}{2} \Omega_{12}^d(t), \quad \Omega_2(t) = \frac{1}{2} \Omega_{21}^d(t) = -Q_{12}^d \Omega_{14}(t).
\]

Using these desired angular velocities, the derivative of the desired relative attitude can be rewritten as

\[
\dot{Q}_{12}^d = Q_{12}^d \Omega_1^d - \Omega_2^d Q_{12}^d.
\]

It is assumed that the desired angular velocities are bounded by known constants.

**Assumption 6:** For known positive constants \( B_d \),

\[
\| \Omega_1^d(t) \| \leq B^d, \quad \| \Omega_2^d(t) \| \leq B^d,
\]

for all \( t \geq 0 \).

The properties of these error variables are summarized as follows.

**Proposition 1:** For positive constants \( k_{12}^\alpha \neq k_{12}^\beta \), define

\[
\Psi_{12} = k_{12}^\alpha \Psi_{12}^\alpha + k_{12}^\beta \Psi_{12}^\beta,
\]

\[
e_{12} = k_{12}^\alpha e_{12}^\alpha + k_{12}^\beta e_{12}^\beta,
\]

\[
e_{21} = k_{21}^\alpha e_{21}^\alpha + k_{21}^\beta e_{21}^\beta,
\]

where \( k_{12}^\alpha = k_{12}^\alpha, k_{21}^\beta = k_{12}^\beta \). The following properties hold:

(i) \( e_{12} = -Q_{21}^d e_{21} \), and \( \| e_{12} \| = \| e_{21} \| \).

(ii) \( \frac{d}{dt} \Psi_{12} = \dot{e}_{12} \cdot e_{\Omega_1} + e_{21} \cdot e_{\Omega_2} \).

(iii) \( \| \dot{e}_{12} \| \leq (k_{12}^\alpha + 2k_{12}^\beta)/(\| e_{\Omega_1} \| + \| e_{\Omega_1} \|) + B^d \| \dot{e}_{21} \|, \)

\[ \| \dot{e}_{21} \| \leq (k_{12}^\beta + 2k_{12}^\alpha)/(\| e_{\Omega_2} \| + \| e_{\Omega_2} \|) + B^d \| \dot{e}_{21} \|. \]

(iv) If \( \Psi_{12} \leq \psi < 2 \min \{ k_{12}^\alpha, k_{12}^\beta \} \) for a constant \( \psi \), then \( \Psi \) is quadratic with respect to \( \| e_{12} \|, \) i.e., the following inequality is satisfied:

\[
\Psi_{12} \| e_{12} \|^2 \leq \Psi_{12} \| e_{12} \|^2, \]

where the constants \( \Psi_{12}, \bar{\Psi}_{12} \) are given by

\[
\Psi_{12} = \frac{2 \max \{ (k_{12}^\alpha)^2, (k_{12}^\beta)^2, (k_{12}^\alpha + k_{12}^\beta)^2 \} + 2(k_{12}^\alpha + k_{12}^\beta)^2}{\min \{ (k_{12}^\alpha)^2, (k_{12}^\beta)^2 \}}, \]

\[
\bar{\Psi}_{12} = \frac{2 \min \{ (k_{12}^\alpha)^2, (k_{12}^\beta)^2 \} (2 \min \{ k_{12}^\alpha, k_{12}^\beta \} - \psi)}{\min \{ (k_{12}^\alpha)^2, (k_{12}^\beta)^2 \} (2 \min \{ k_{12}^\alpha, k_{12}^\beta \} - \psi)}.\]

**Proof:** See [16].

Using these properties, we develop a control system to track the given desired relative attitude as follows.

**Proposition 2:** Consider the attitude dynamics of spacecraft given by (6), (7) for \( i \in \{ 1, 2 \} \), with the LOS measurements specified at (8). A desired relative attitude trajectory is given by (10). For positive constants \( k_{12}^\alpha \neq k_{12}^\beta, k_{21}^\alpha = k_{12}^\beta, k_{21}^\beta = k_{12}^\alpha, k_{12} \), control inputs are chosen as

\[
u_i = -e_{ij} - k_{ij} e_{\Omega_i} + \dot{q}_{ij}^d J_i (e_{\Omega_i} + \Omega_{ij}^d) + J_{ij} \dot{\Omega}_i,\]

where \( (i, j) \in E \). Then, the following properties hold:

(i) There are four types of equilibrium, given by the desired equilibrium \( (Q, \Omega_1) = (Q_{12}^d, \Omega_1^d) \), and the relative configurations represented by \( Q_{ij}^d = R_{i}^d U D U^T R_1 \) and \( \Omega_{ij} = \Omega_{ij}^d \) where \( D \in \{ \text{diag}[1, -1, -1], \text{diag}[-1, 1, -1], \text{diag}[-1, -1, 1] \} \) and \( U \in SO(3) \) is the matrix composed of eigenvectors of \( K_{12} = k_{12}^\alpha s_{12}s_{12}^T + k_{12}^\beta s_{12}s_{12}^T \).

(ii) The desired equilibrium is almost globally exponentially stable, and a (conservative) estimate to the region of attraction is given by

\[
\Psi_{ij}(0) < \psi < 2 \min \{ k_{12}^\alpha, k_{12}^\beta \},
\]

\[ \sum_{i=1,2} \lambda_i \| e_{\Omega_i}(0) \|^2 < 2(\psi - \Psi_{ij}(0)), \]

where \( \psi \) is a positive constant satisfying \( \psi < 2 \min \{ k_{12}^\alpha, k_{12}^\beta \} \), and \( \lambda_i \) denotes the maximum eigenvalue of \( J_i \).

(iii) The undesired equilibria are unstable.

**Proof:** See [16].

This states that almost all solutions of the proposed control system, excluding a class of solutions starting from a specific set that has a zero-measure, asymptotically track the desired relative attitude. As the control inputs are expressed in terms of LOS observations, in addition to angular velocities, and the full relative attitude does not have to be constructed at each time. These results can be considered as a generalization of the preliminary work in [13], but it is a nontrivial extension as the several properties of the error variables should be considered to show a stronger exponential stability for tracking problems.

**IV. RELATIVE ATTITUDE FORMATION TRACKING**

The relative attitude control system between two spacecraft developed in the previous section can be used as a building block for a relative attitude formation control system for multiple spacecraft. In this section, we generalize it for daisy-chained relative attitude formation control network.

**A. Relative Attitude Tracking Between Three Spacecraft**

We first consider relative attitude formation tracking between three spacecraft, given by Spacecraft 1, 2, and 3, illustrated at Figure 1. The corresponding edge set and the assignment set used in this subsection are given by

\[
\mathcal{E} = \{ (1, 2), (2, 1), (2, 3), (3, 2) \},
\]

\[ \mathcal{A} = \{ (1, 2, 3), (2, 1, 3), (2, 3, 1), (3, 2, 1) \}. \]

For given relative attitude commands, \( Q_{ij}^d(t), Q_{23}^d(t) \), the goal is to design control inputs such that \( Q_{12}(t) \rightarrow Q_{12}^d(t) \) and \( Q_{23}(t) \rightarrow Q_{23}^d(t) \) as \( t \rightarrow \infty \).

The definition of error variables and their properties developed in the previous section for two spacecraft are readily
generalized to any \((i, j, k) \in \mathcal{A}\) in this section. For example, the kinematic equation for the desired relative attitude \(Q_{23}^d\) is obtained from (10) as

\[
\dot{Q}_{23}^d = Q_{23}^d \hat{\Omega}_{23},
\]

where \(\hat{\Omega}_{23}\) is the desired relative angular velocity. Other configuration error functions and error vectors between Spacecraft 2 and Spacecraft 3 are defined similarly.

The desired absolute angular velocities for each spacecraft, namely \(\Omega_{12}^d\), \(\Omega_{23}^d\), and \(\Omega_{45}^d\) should be properly defined. For the given \(\Omega_{12}^d\), \(\Omega_{23}^d\), they can be arbitrarily chosen such that

\[
\begin{align*}
\Omega_{12}^d(t) &= \Omega_{11}^d(t) - Q_{21}^d(t)\Omega_{21}^d(t), \\
\Omega_{23}^d(t) &= \Omega_{22}^d(t) - Q_{32}^d(t)\Omega_{32}^d(t).
\end{align*}
\]

For example, they can be chosen as \(\Omega_1^d = \Omega_2^d = 0\), \(\Omega_{12}^d = -Q_{23}^d\Omega_{23}^d\). Assumption 6 is considered to be satisfied such that each of the desired angular velocity is bounded by a known constant \(B^d\).

**Proposition 3:** Consider the attitude dynamics of spacecraft given by (6), (7) for \(i \in \{1, 2, 3\}\), with the LOS measurements specified at (33). Desired relative attitudes are given by \(Q_{12}^d(t), Q_{23}^d(t)\). For positive constants \(k_{ij}, k_{ij}^d, k_{ji}\) with \(k_{ij}^d \neq k_{ij}, k_{ij} = k_{ji}^d = k_{ji}^d\) for \((i, j) \in \mathcal{E}\),

\[
\begin{align*}
&u_1 = -e_{21} - k_{12}e_{12} + \hat{\Omega}_{12}^dJ_1(e_{12} + \Omega_{12}^d) + J\hat{\Omega}_{12}^d, \\
&u_2 = -\frac{1}{2}(e_{23} + e_{21}) - k_{12}e_{12} + \hat{\Omega}_{22}^dJ_2(e_{12} + \Omega_{22}^d) + J\hat{\Omega}_{22}^d, \\
&u_3 = -e_{32} - k_{12}e_{12} + \hat{\Omega}_{32}^dJ_3(e_{12} + \Omega_{32}^d) + J\hat{\Omega}_{32}^d.
\end{align*}
\]

Then, the desired relative attitude configuration is almost globally exponentially stable, and a (conservative) estimate to the region of attraction is given by

\[
\begin{align*}
\Psi_{12}(0) + \Psi_{23}(0) &\leq \psi < 2\min\{k_{12}, k_{12}^d, k_{23}, k_{23}^d\}, \\
\lambda_M||e_{12}(0)||^2 &+ 2\lambda_M||e_{12}(0)||^2 + \lambda_M||e_{12}(0)||^2 \\
&\leq 2(\psi - \Psi_{12}(0) - \Psi_{23}(0)),
\end{align*}
\]

where \(\psi\) is a positive constant satisfying \(\psi < 2\min\{k_{12}, k_{12}^d, k_{23}, k_{23}^d\}\).

**Proof:** See [16].

The control inputs for Spacecraft 1 and Spacecraft 3 at the both ends of graph are identical to (29) at Proposition 2. The control input for Spacecraft 2, which are paired with both of Spacecraft 1 and 3, is also similar to (29) except that the configuration error vectors for Spacecraft 2, namely \(e_{23}\) and \(e_{23}\) are averaged. These ideas can be generalized to relative attitude formation tracking between an arbitrary number of spacecraft as follows.

**B. Relative Attitude Formation Tracking Between \(n\) Spacecraft**

Consider a formation of \(n\) spacecraft, i.e., \(\mathcal{N} = \{1, \ldots, n\}\). According to Assumption 5, spacecraft are paired serially in the edge set. For convenience, it is assumed that spacecraft are numbered such that the edge set is given by

\[
\mathcal{E} = \{(1, 2), \ldots, (n-1, n), (2, 1), \ldots, (n, n-1)\}.
\]

The assignment set is given by (3) for an arbitrary assignment map satisfying Assumption 2. The desired relative attitudes \(Q_{ij}^d\) for \((i, j) \in \mathcal{E}\) are prescribed. The definition of error variables and their properties developed in Section III are generalized to any \((i, j, k) \in \mathcal{A}\). The desired absolute angular velocities \(\Omega_i^d\) for \(i \in \mathcal{N}\) are chosen such that

\[
\Omega_{ij}^d(t) = \Omega_i^d(t) - Q_{ij}^d(t)\Omega_{ij}^d(t) \quad \text{for} \quad (i, j) \in \mathcal{E}.
\]

**Proposition 4:** Consider the attitude dynamics of spacecraft given by (6), (7) for \(i \in \{1, \ldots, n\}\), with the LOS measurements specified by (41),(3). Desired relative attitudes are given by \(Q_{ij}^d(t)\) for \((i, j) \in \mathcal{E}\). For positive constants \(k_{ij}, k_{ij}^d, k_{ji}\) with \(k_{ij}^d \neq k_{ij}, k_{ij} = k_{ji}^d, k_{ji} = k_{ji}^d\), the control inputs chosen as

\[
\begin{align*}
&u_1 = -e_{12} - k_{12}e_{12} + \hat{\Omega}_{12}^dJ_1(e_{12} + \Omega_{12}^d) + J\hat{\Omega}_{12}^d, \\
&u_p = -\frac{1}{2}(e_{p,p-1} + e_{p,p+1}) - k_{12}e_{12} + \hat{\Omega}_{p2}^dJ_p(e_{12} + \Omega_{p2}^d) + J\hat{\Omega}_{p2}^d, \\
&u_n = -e_{n,n-1} - k_{12}e_{12} + \hat{\Omega}_{n2}^dJ_n(e_{12} + \Omega_{n2}^d) + J\hat{\Omega}_{n2}^d.
\end{align*}
\]

Then, the desired relative attitude configuration is almost globally exponentially stable.

**Proof:** See [16].

**V. NUMERICAL EXAMPLE**

Consider the formation of seven spacecraft illustrated at Figure 2. The corresponding edge is given by (41) with \(n = 7\), and the assignment set is

\[
\mathcal{A} = \{(1, 2, 3), (2, 1, 3), (2, 3, 4), (3, 2, 4), (3, 4, 5), (4, 3, 5), (4, 5, 7), (5, 4, 7), (5, 6, 7), (6, 5, 7), (6, 7, 5), (7, 6, 5)\}.
\]

The desired relative attitudes for \(Q_{34}^d\) and \(Q_{45}^d\) are given in terms of 3-2-1 Euler angles as \(Q_{34}^d(\alpha(t), \beta(t), \gamma(t))\), \(Q_{45}^d(t) = Q_{45}^d(\phi(t), \theta(t), \psi(t))\), where

\[
\begin{align*}
\alpha(t) &= \sin 0.5t, \quad \beta(t) = 0.1, \quad \gamma(t) = \cos t, \\
\phi(t) &= 0, \quad \theta(t) = -0.1 + \cos 0.2t, \quad \psi(t) = 0.5 \sin 2t,
\end{align*}
\]

4831
and $Q_{ij}^*(t) = Q_{ij}^d(t) = Q_{ii}^d(t) = I$, $Q_{id}^d(t) = (Q_{id}^d(t))^T$. It is chosen that $\Omega_{ij}^d(t) = 0$, and other desired absolute angular velocities are selected to satisfy (42).

The initial attitudes for Spacecraft 3 and 6 are chosen as $R_3(0) = \exp(0.999\pi\hat{e}_1)$ and $R_6(0) = \exp(0.990\pi\hat{e}_2)$, where $\hat{e}_1 = [1, 0, 0]^T, \hat{e}_2 = [0, 1, 0]^T \in \mathbb{R}^3$. The initial attitudes for other spacecraft are chosen as the identity matrix. The resulting initial errors for the relative attitudes $Q_{23}$ and $Q_{67}$ are $0.99\pi \text{ rad} = 179.82^\circ$. The initial angular velocity is chosen as zero for every spacecraft.

The inertia matrix is identical, i.e., $J_i = \text{diag}[3, 2, 1] \text{ kgm}^2$ for all $i \in \mathcal{N}$. Controller gains are chosen as $k_{23} = 7$, $k_{67} = 25$, and $k_{ij} = 25.1$ for any $(i, j) \in \mathcal{E}$.

In numerical simulations, an image processing routine is incorporated, as illustrated at Figure 3. A virtual image observed from Spacecraft 4 is generated based on the relative positions and its attitude $R_4$. The generated image is processed online to find the locations of Spacecraft 3 and 7 in the two-dimensional image plane, and it is transformed into the body-fixed frame of Spacecraft 4 to obtain $b_{43}, b_{47}$. This is to test the feasibility of the proposed vision-based spacecraft relative attitude formation control scheme with numerical simulations integrated with image processing.

The corresponding numerical results are illustrated at Figures 5 and 4. Tracking errors for relative attitudes and control inputs are shown at Figure 5, where the relative attitude error vectors are defined as $\epsilon Q_{ij} = \frac{1}{2}((Q_{ij}^d)^TQ_{ij} - Q_{ij}Q_{ij}^d)^\vee \in \mathbb{R}^3$. These illustrate good convergence rates. Virtual images observed from Spacecraft 4 at few times are also shown at Figure 4.
