Remarks on diffusive-link synchronization using non-Hilbert logarithmic norms

Zahra Aminzare† and Eduardo D. Sontag‡

Abstract—In this paper, we sketch recent results for synchronization in a network of identical ODE models which are diffusively interconnected. In particular, we provide estimates of convergence of the difference in states between components, in the cases of line, complete, and star graphs, and Cartesian products of such graphs.

I. INTRODUCTION

The analysis of synchrony in networks of identical components is a long-standing problem in different fields of science and engineering as well as in mathematics.

We will restrict attention to interconnections given by diffusion, where each pair of “adjacent” components exchange information and adjust in the direction of the difference with each other. Our approach is based on the use of logarithmic norms (also called matrix measures), often called the “contraction” approach.

The proof of synchronization results using contraction-based techniques is in itself not new, though most results restrict to measures derived from $L^2$ or weighted $L^2$ norms, see for example [1], [2], [3], [4], [5].

We base our approach on contraction theory, using matrix measures derived from norms that are not induced by inner products ($L^2$ and weighted $L^2$).

II. SYNCHRONIZATION IN A SYSTEM OF ODES

We will use the following concepts and notations throughout this paper:

- For a fixed convex subset of $\mathbb{R}^n$, say $V$, $\bar{F} : V^N \times [0, \infty) \rightarrow \mathbb{R}^{nN}$ is a function of the form:
  $$\bar{F}(x, t) = (F(x_1, t)^T, \ldots, F(x_N, t)^T)^T,$$
  where $x = (x_1^T, \ldots, x_N^T)^T$, with $x_i \in V$ for each $i$, and $\bar{F}(\cdot, t) := \bar{F}_t : V \rightarrow \mathbb{R}^n$ is a $C^1$ function.
- For any $x \in V^N$ we define $\|x\|_{p,Q}$ as follows:
  $$\|x\|_{p,Q} = \left(\|Qx_1\|_p, \ldots, \|Qx_N\|_p\right)^T,$$
  for any positive diagonal matrix $Q = \text{diag}(q_1, \ldots, q_n)$ and $1 \leq p \leq \infty$.

When $N = 1$, we simply have a norm in $\mathbb{R}^n$:
$$\|x\|_{p,Q} := \|Qx\|_p.$$
and \( J_F(\cdot, t) \) denotes the Jacobian of \( F \) with respect to the first variable. Then

\[
\| (E^T \otimes I) x(t) \| \leq e^{ct} \| (E^T \otimes I) x(0) \|
\]

where \( \| \cdot \| \) is the given norm on \( \mathbb{R}^{mn} \). In particular, when \( c < 0 \), the system synchronizes, i.e., for any pair \( (i, j) \), \((x_i - x_j)(t) \to 0 \) as \( t \to \infty \).

Note that \((E^T \otimes I) x\) is a column vector whose entries are the differences \( x_i - x_j \), for each edge \( e = (i, j) \) in \( G \).

For instance, for a linear graph of \( n \) nodes and the incidence matrix
\[
E = \begin{pmatrix} -1 & 0 \\ 1 & -1 \\ 0 & 1 \end{pmatrix}, \quad (E^T \otimes I) x = \begin{pmatrix} x_2 - x_1 \\ x_3 - x_2 \end{pmatrix}.
\]

The results in the following sections, (Proposition 1 and Proposition 2) are direct applications of Theorem 1.

We next specialize to the linear case, when \( F(x, t) = A(t)x \).

**Theorem 2:** Consider a \( G \)-componentartment system, \((F, G, D)\), and suppose that \( F(x, t) = A(t)x \), i.e.,

\[
\dot{x}(t) = (I \otimes A(t) - \mathcal{L} \otimes D) x(t).
\]

For a given arbitrary norm on \( \mathbb{R}^n \), \( \| \cdot \| \), suppose that

\[
\sup_{t} M[A(t) - \lambda_2 D] < 0,
\]

where \( \lambda_2 \) is the smallest nonzero eigenvalue of the Laplacian matrix \( \mathcal{L} \) and \( M \) is the logarithmic norm induced by \( \| \cdot \|. \)

Then, for any \( i, j \in \{1, \ldots, N\} \), \((x_i - x_j)(t) \to 0 \), exponentially as \( t \to \infty \).

For \( L^2 \) norms, this linear result can also be interpreted in terms of Lyapunov exponents or characterized using Nyquist plots, see for example [7], [8].

While the results for measures based on Euclidean norm are quite general, in the nonlinear case and for \( L^p \) norms, \( p \neq 2 \), we only have special cases to discuss, depending on the graph structure. We present sufficient conditions for synchronization for some special graphs (linear, complete, star), and compositions of them (Cartesian product graphs).

See Table I and Table II for a summary of the results that will be stated in this section and proved in [6].

### A. Linear Graphs

In this section, we study a \( G \)-componentartment system, where \( G \) is a linear graph of \( N \) nodes.

Assuming \( x_0 = x_1, x_{N+1} = x_N \), the following system of ODEs describes the evolution of the individual agent \( x_i \), for \( i = 1, \ldots, N \):

\[
\dot{x}_i = F(x_i, t) + D(x_{i-1} - x_i + x_{i+1} - x_i). \tag{3}
\]

**Proposition 1:** Let \((x_1, \ldots, x_N) \) be a solution of (3), and for \( 1 \leq p \leq \infty \) and a positive diagonal matrix \( Q \), let

\[
c = \sup_{(x,t)} M_{p,Q} [J_F(x, t) - 4 \sin^2(\pi/2N)D]. \tag{4}
\]

Then

\[
\|e(t)\|_{p,Q,K} \leq e^{ct} \|e(0)\|_{p,Q,K}, \tag{5}
\]

where \( e = (x_1 - x_2, \ldots, x_{N-1} - x_N)^T \) denotes the vector of all edges of the linear graph, and \( \| \cdot \|_{p,Q,K} \) denotes the weighted \( L^p \) norm with the weight \( Q_k \otimes Q \), for any \( 1 \leq p \leq \infty \).

\[
Q_p = \text{diag} \left( \frac{2\pi}{p_1}, \ldots, \frac{2\pi}{p_N} \right)
\]

and for \( 1 \leq k \leq N - 1 \), \( p_k = \sin(k\pi/N) \). In addition, \( 4\sin^2(\pi/2N) \) is the smallest nonzero eigenvalue of the Laplacian matrix of \( G \). Note that, \( Q_{\infty} = \text{diag} \left( 1/p_1, \ldots, 1/p_{N-1} \right) \).

To see a proof of Proposition 1 and how \( c \) in Proposition 1 is related to \( c \) in Theorem 1, see [6].

The significance of Proposition 1 is as follows: since the numbers \( \sin(k\pi/N) \) are nonzero, we have, when \( c < 0 \), exponential convergence to uniform solutions in a weighted \( L^p \) norm, the weights being specified in each compartment by the matrix \( Q \) and the relative weights among compartments being weighted by the functions \( \sin(k\pi/N) \).

**Remark 1:** Under the conditions of Proposition 1, the following inequality holds:

\[
\sum_{i=1}^{N-1} \|e_i(t)\|_{p,Q} \leq \alpha e^{ct} \sum_{i=1}^{N-1} \|e_i(0)\|_{p,Q},
\]

where \( \alpha = \max_k \{(Q_p)_{kk}^{-1} \} \left( (N - 1)^{-1/p} - 1 \right) > 0 \), and \((Q_p)_{kk}\) is the \( k \)th diagonal entry of \( Q_p \).

### B. Complete Graphs

Now consider a \( G \)-componentartment system, where \( G \) is a complete graph of \( N \) nodes.

The following system of ODEs describes the evolution of the interconnected agents \( x_i \)’s:

\[
\dot{x}_i = F(x_i, t) + D \sum_{j=1}^{N} (x_j - x_i) \tag{6}
\]

**Proposition 2:** Let \( \| \cdot \| \) be an arbitrary norm on \( \mathbb{R}^n \). Suppose \((x_1, \ldots, x_m) \) is a solution of Equation (6) and let

\[
c := \sup_{(x,t)} M[J_F(x, t) - ND]
\]

where \( M \) is the logarithmic norm induced by \( \| \cdot \| \). Then

\[
\sum_{i=1}^{m} \|e_i(t)\| \leq e^{ct} \sum_{i=1}^{m} \|e_i(0)\|,
\]

where \( e_i \), for \( i = 1, \ldots, m \) are the edges of \( G \), meaning the differences \( x_i(t) - x_j(t) \) for \( i < j \).

In particular, when \( c < 0 \), (6) synchronizes.

To prove Proposition 2, we need the following lemma (see [6] for a proof).

**Lemma 1:** Let \( A \) be an \( mn \times mn \) block diagonal matrix with \( n \times n \) matrices \( A_1, \ldots, A_m \) on its diagonal. Let \( \| \cdot \| \)
TABLE I: Sufficient conditions for synchronization in complete, line and star graphs of $N$ nodes. If no subscript is used in $M$, the result has been proved for arbitrary norms.

be an arbitrary norm on $\mathbb{R}^n$ and define $\| \cdot \|_*$ on $\mathbb{R}^{mn}$ as follows. For any $e = (e_1^T, \ldots, e_m^T)^T$ with $e_i \in \mathbb{R}^n$, and any $1 \leq p \leq \infty$, $\| e \|_* := \left( \| e_1 \|_1^p, \ldots, \| e_m \|_1^p \right)^{1/p}$. Then

$$M_\ast[A] \leq \max \{ M[A_1], \ldots, M[A_m] \},$$

where $M$ and $M_\ast$ are the logarithmic norms induced by $\| \cdot \|$ and $\| \cdot \|_*$ respectively.

**Proof of Proposition 2** The following $N \times N$ matrix indicates the (graph) Laplacian matrix of a complete graph of $N$ nodes,

$$\mathcal{L} = \begin{pmatrix}
N - 1 & -1 & \ldots & -1 \\
-1 & N - 1 & \ldots & -1 \\
\vdots & & \ddots & \\
-1 & \ldots & -1 & N - 1
\end{pmatrix},$$

with $\lambda_1 = 0$ and $\lambda_2 = N$. Let $E$ be an incidence matrix of $G$. We first show that $E^T E E^T = N E^T$. For any orientation of $G$, $E^T$ is an $\binom{N}{2} \times N$ matrix such that its $i$–th row looks like $(\epsilon_{i1}, \ldots, \epsilon_{iN})$, where for exactly one $j$, $\epsilon_{ij} = 1$, for exactly one $j$, $\epsilon_{ij} = -1$, and for the rest of $j$'s, $\epsilon_{ij} = 0$. Observe that for any row $i$, $\sum_j \epsilon_{ij} = 0$, and

$$\begin{pmatrix} E^T \mathcal{L} \end{pmatrix}_{(ij)} = \begin{pmatrix} E^T \end{pmatrix}_{(i)} \begin{pmatrix} \mathcal{L} e_j \end{pmatrix},$$

where $(A)_{(ij)}$ denotes the $(i,j)$–th entry of matrix $A$, and $(A)_{r_i}$ and $(A)_{c_i}$ denote the $i$th row and $i$th column of $A$, respectively. Hence,

$$\begin{pmatrix} E^T \mathcal{L} \end{pmatrix}_{(ij)} = \begin{pmatrix} \epsilon_{i1}, \ldots, \epsilon_{iN} \end{pmatrix} \begin{pmatrix} -1 \\
\vdots \\
N - 1 \\
\vdots \\
-1 \end{pmatrix} \leftarrow j^{th}$$

6088
This proves $E^T \mathcal{L} = E^T E E^T = N E^T$. Thus we may apply Theorem 1 with $K = N I$. Then $\mathcal{J} := J(w, t) - K \otimes D$ can be written as follows:

$$\mathcal{J} = \begin{pmatrix} J_F(w_1, t) - ND & \cdots & 0 \\
0 & \ddots & \vdots \\
0 & \cdots & J_F(w_m, t) - ND \end{pmatrix}. $$

For $u = (u_1, \ldots, u_m)^T$, with $u_i \in \mathbb{R}^n$, let $\|u\|_* := \left( \sum_1^n \|u_i\|_1 \right)^T$, where $\| \cdot \|_1$ is $L^1$ norm on $\mathbb{R}^m$, and let $M_\ast$ be the logarithmic norm induced by $\| \cdot \|_*$. Then by the definition of $M_\ast$ and Lemma 1,

$$M_\ast[J(w, t) - K \otimes D] \leq \max_i \left\{ M[J_F(w_i, t) - N D] \right\}. $$

Therefore, by taking sup over all possible $w$’s in both sides of the above inequality, we get:

$$\sup_w M_\ast[J(w, t) - K \otimes D] \leq \sup_{(x, t)} M[J_F(x, t) - ND] = c. $$

Applying Theorem 1, we conclude the desired result.

### C. Star Graphs

Now consider a $G$–compartment system, where $G$ is a star graph of $N + 1$ nodes.

The following system of ODEs describe the evolution of the $x_i$’s:

$$\begin{align*}
\dot{x}_i &= F(x_i, t) + D (x_0 - x_i), \quad i \neq 0 \\
\dot{x}_0 &= F(x_0, t) + D \sum_{i \neq 0} (x_i - x_0)
\end{align*}$$

**Proposition 3:** Let $(x_0, \ldots, x_N)$ be a solution of (7) and $c := \sup_{(x, t)} M[J_F(x, t) - D]$, where $M$ is the logarithmic norm induced by an arbitrary norm $\| \cdot \|$ on $\mathbb{R}^n$. Then for any $i \in \{1, \ldots, N\}$,

$$\|x_i - x_0(t)\| \leq (1 + \alpha_i t) e^{ct} \|x_i - x_0(0)\|$$

where $\alpha_i = \sum_{j \neq i, 0} \|x_j - x_i(0)\|$.

In particular, when $c < 0$, for any $i = 1, \ldots, N$, $(x_i - x_0(t)) \to 0$ exponentially as $t \to \infty$.

Note that the smallest non-zero eigenvalue of the Laplacian matrix of $G$ is 1.

**Remark 2:** Under the conditions of Proposition 3, the following inequality holds:

$$\sum_{i \neq 0} \|x_i - x_0(t)\| \leq P e^{ct} \sum_{i \neq 0} \|x_i - x_0(0)\|$$

where $P = 1 + 2(N - 1) t \sum_{i \neq 0} \|x_i - x_0(0)\|$.

### D. Cartesian products

For $k = 1, \ldots, K$, let $G_k = (V_k, E_k)$ be an arbitrary graph, with $|V_k| = N_k$ and Laplacian matrix $L_{G_k}$.

Consider a system consisting of $N = \prod_{k=1}^K N_k$ compartments, where we denote state variables as $x_{i_1, \ldots, i_K} \in \mathbb{R}^n$, $i_j = 1, \ldots, N_j$, which are interconnected by a Cartesian product $G = G_1 \times \cdots \times G_K$ of the $K$ graphs $G_j$. The following system of ODEs describe the evolution of $x_{i_1, \ldots, i_K}$:

$$\dot{x} = \tilde{F}(x, t) - \mathcal{L} \otimes D x$$

where $x = (x_{i_1, \ldots, i_K})$ is the vector of all $N$ compartments, $\tilde{F}(x, t) = (F(x_{i_1, \ldots, i_K}, t))$, $\mathcal{L}$ is defined as follows:

$$\sum_i I_{N_k} \otimes \cdots \otimes L_{G_k} \otimes \cdots \otimes I_{N_1},$$

and the $n \times n$ matrix $D$ is the diffusion matrix.

**Proposition 4:** Given graphs $G_k$, $k = 1, \ldots, K$ as above, suppose that for each $k$, there are a norm $\| \cdot \|_{(k)}$ on $\mathbb{R}^n$, a real nonnegative number $\lambda_{(k)}$, and a polynomial $P_{(k)}(z, t)$ on $\mathbb{R}_{\geq 0}^n$, with the property that for each $z$, $P_{(k)}(z, 0) \geq 0$, such that for every solution $x$ of (9),

$$\sum_{e \in E_k} \| e(t) \|_{(k)} \leq P_{(k)} e^{c_k t} \sum_{e \in E_k} \| e(0) \|_{(k)}$$

holds, where

$$P_{(k)} = P_{(k)} \left( \sum_{e \in E_k} \| e(0) \|_{(k)} , t \right)$$

and $c_k := \sup_{(x, t)} M_{(k)} [J_F(x, t) - \lambda_{(k)} D]$, and $M_{(k)}$ is the logarithmic norm induced by $\| \cdot \|_{(k)}$. Then for any norm $\| \cdot \|$ on $\mathbb{R}^n$, there exists a polynomial $P(z, t)$ on $\mathbb{R}_{\geq 0}^n$, with the property that for each $z$, $P(z, 0) \geq 1$, such that

$$\sum_{e \in E} \| e(t) \| \leq P \left( \sum_{e \in E} \| e(0) \| , t \right) e^{ct} \sum_{e \in E} \| e(0) \|,$$

where $c := \max\{c_1, \ldots, c_k\}$, and $E$ is the set of the edges of $G$. Observe that if all $c_i < 0$, then also $c < 0$, and this guarantees synchronization, as all $e(t) \to 0$.

Note that for $K = 1$, Remark 1, Proposition 2, and Remark 2 show that (10) holds when $G_k$ is a line, complete or star graph, for $P_{(k)}(z, t) = \alpha, 1 + 2(N - 1)t z$, respectively. Therefore, for a hypercube (cartesian product of $K$ line graphs) with $N_1 \times \cdots \times N_K$ nodes, if for given norm on $\mathbb{R}^n$, $\| \cdot \|$, and $\lambda_2 = \min_i \{\lambda_{(i)}\}$,

$$\sup_{(x, t)} M [J_F(x, t) - \lambda_2 D] < 0,$$

where $M$ is the logarithmic norm induced by $\| \cdot \|$, then the system synchronizes. See Table II.

Also, for a Rook graph (cartesian product of $K$ complete graphs) of $N_1 \times \cdots \times N_K$ nodes, if for any given norm, and $\lambda_2 = \min_i \{\lambda_{(i)}\}$,

$$\sup_{(x, t)} M [J_F(x, t) - \lambda_2 D] < 0,$$
then the system synchronizes. See Table II.

As an application of Cartesian products, we specifically study the Cartesian product of two linear graphs, i.e. a grid graph, as follows:

Consider a network of $N_1 \times N_2$ compartments that are connected to each other by a 2-D, $N_1 \times N_2$ lattice (grid) graph $G = (V, E)$, where

$$V = \{x_{ij}, \ i = 1, \ldots, N_1, \ j = 1, \ldots, N_2\}$$

is the set of all vertices and $E$ is the set of all edges of $G$.

The following system of ODEs describes the evolution of the $x_{ij}$'s: for any $i = 1, \ldots, N_1$, and $j = 1, \ldots, N_2$

$$\dot{x}_{ij} = F(x_{ij}, t) + D\left(x_{i-1,j} - 2x_{i,j} + x_{i+1,j}\right)$$

$$+ D\left(x_{i,j-1} - 2x_{i,j} + x_{i,j+1}\right), \quad (11)$$

assuming Neumann boundary conditions, i.e. $x_{i,0} = x_{i,1}$, $x_{i,N_2} = x_{i,N_2+1}$, etc.

**Proposition 5:** Let $x = \{x_{ij}\}$ be a solution of Equation (11) and $c = \max\{c_1, c_2\}$, where for $i = 1, 2$,

$$c_i := \sup_{(x,t)} M_{p,Q} \left[J_F(x,t) - 4\sin^2(\pi N_i) D\right],$$

and $1 \leq p \leq \infty$. Then, there exist positive constants $\alpha \geq 1$, and $\beta$ such that

$$\sum_{e \in E} \|e(t)\|_{p,Q} \leq (\alpha + \beta t) e^\alpha \sum_{e \in E} \|e(0)\|_{p,Q}. \quad (12)$$

In particular, when $c < 0$, the system (11) synchronizes, i.e., for all $i, j, k, l$

$$(x_{ij} - x_{kl})(t) \to 0, \mbox{ exponentially as } t \to \infty.$$ See [6] for a proof.

One can get the analogous result for the Cartesian products of $K \geq 2$ linear graphs.

### III. An Example

**Goodwin Oscillator**

In 1965, Brian Goodwin proposed a differential equation model, that describes the generic model of an oscillating autoregulatory gene, and studied its oscillatory behavior [9].

The following systems of ODEs is a variant of Goodwin's model [10]:

$$\begin{align*}
\frac{dx}{dt} &= \frac{a}{k + z(t)} - bx(t) \\
\frac{dy}{dt} &= \alpha x(t) - \beta y(t) \\
\frac{dz}{dt} &= -\gamma y(t) - \delta z(t)
\end{align*} \quad (13)$$

The model, sketched in Fig. 1a, in the original paper represented a single gene with mRNA, $X$, which is translated into an enzyme, $Y$, which in turn, catalyses production of a metabolite, $Z$. Finally, the metabolite inhibits the expression of the original gene. However the model is quite generic.

Fig. 1b shows the oscillatory solutions of (13) for 6 different initial conditions for the following parameter values from [11]:

$a = 150$, $k = 1$, $b = \alpha = \beta = \gamma = 0.2$, $\delta = 15$, $K_M = 1$.

Fig. 1c shows the solutions of the same system (6 compartments with the same initial conditions as in Fig. 1b) that are interconnected diffusively by a linear graph and they all synchronize. Note that only $X$ is interconnected to other $X$'s in the graph, i.e. $D = \text{diag}(d, 0, 0)$. The following system of ODEs describes the evolution of compartments:

For each compartment $i = 1, \ldots, N$ (here $N = 6$):

$$\begin{align*}
\frac{dx_i}{dt} &= \frac{a}{k + z_i(t)} - bx_i(t) + d(x_{i-1} - 2x_i + x_{i+1}) \\
\frac{dy_i}{dt} &= \alpha x_i(t) - \beta y_i(t) \\
\frac{dz_i}{dt} &= \gamma y_i(t) - \frac{\delta z_i}{k_M + z_i(t)}
\end{align*} \quad (14)$$

assuming $x_0 = x_1$ and $x_N = x_{N+1}$.

Fig. 1d shows the solutions of the same system (6 compartments with the same initial conditions as in Fig. 1b) that are interconnected diffusively by a complete graph, using again $D = \text{diag}(d, 0, 0)$. Comparing Fig. 1b and Fig. 1d shows that the subsystems synchronize faster when they are connected by a complete graph.

### IV. Discussion

In this conference paper, we established new results for synchronization in a network of identical ODE models which are diffusively interconnected. We provided estimates of convergence of the difference in states between components, in the cases of line, complete, and star graphs, and Cartesian products of such graphs. A journal version will provide more details and proofs.

In [12], [6], we also provide analogous results for convergence to uniform solutions in reaction-diffusion partial differential equations:

$$\dot{u} = F(u, t) + D\Delta u. \quad (14)$$

These results require the use of techniques from nonlinear functional analysis for normed spaces, in contrast to tools appropriate for Hilbert spaces. An example of one such a result is as follows.

**Theorem 3:** Let $u(\omega, t)$ be a solution of (14), subject to Neumann boundary conditions, defined for all $t \in [0, T)$ for some $0 < T \leq \infty$, and $\omega \in (0, L)$. In addition, assume that $u(\cdot, t) \in C^3(\Omega)$, for all $t \in [0, T)$. Let

$$c = \sup_{(x,t)} M_{1,Q,\phi} \left[J_{F_1}(x) - \frac{\pi^2}{L^2} D\right],$$

where $M_{1,Q,\phi}$ is the logarithmic norm induced by the following norm:

$$\|\cdot\|_{1,Q,\phi} := \|\sin(\pi \omega/L)(\cdot)\|_{1,Q}.$$

6090
Then for all $t \in [0, T)$:

$$
\left\| \frac{\partial u}{\partial \omega}(\cdot, t) \right\|_{1,Q,\phi} \leq e^{ct} \left\| \frac{\partial u}{\partial \omega}(\cdot, 0) \right\|_{1,Q,\phi}.
$$

Note that $-\pi^2/L^2$ is equal to the second Neumann eigenvalue of the Laplacian operator on $(0, L)$.

The significance of Theorem 3 lies in the fact that $\sin(\pi\omega/L)$ is nonzero everywhere in the domain (except at the boundary). In that sense, we have exponential convergence to uniform solutions in a weighted $L^1$ norm.
